Abstract: Synthesis, isolation, and structural characterization of unique metal rich diamagnetic cobaltaborane clusters are reported. They were obtained from reactions of monoborane as well as modified borohydride reagents with cobalt sources. For example, the reaction of $[\text{Cp}^*\text{CoCl}]_2$ with $[\text{LiBH}_4 \cdot \text{THF}]$ and subsequent photolysis with excess $[\text{BH}_3 \cdot \text{THF}]$ (THF = tetrahydrofuran) at room temperature afforded the 11-vertex tricobaltaborane *nido*- $[(\text{Cp}^*\text{Co})_3\text{B}_8\text{H}_{10}]$ (**1**, $\text{Cp}^* = \eta^5\text{-C}_5\text{Me}_5$). The reaction of $\text{Li}[\text{BH}_2\text{S}_3]$ with the dicobaltoctaborane(12) $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{H}_{10}]$ yielded the 10-vertex *nido*-2,4- $[(\text{Cp}^*\text{Co})_2\text{B}_8\text{H}_{12}]$ cluster (**2**), extending the library of dicobaltadecaborane(14) analogues. Although cluster **1** adopts a *classical* 11-vertex-*nido*-geometry with one cobalt center and four boron atoms forming the open pentagonal face, it disobeys the Polyhedral Skeletal Electron Pair Theory (PSEPT). Compound **2** adopts a perfectly symmetrical 10-vertex-*nido* framework with a plane of symmetry bisecting the basal boron plane resulting in two $\{\text{CoB}_3\}$ units bridged at the base by two boron atoms and possesses the expected electron count. Both compounds were characterized in solution by multinuclear NMR and IR spectroscopies and by mass spectrometry. Single-crystal X-ray diffraction analyses confirmed the structures of the compounds. Additionally, density functional theory (DFT) calculations were performed in order to study and interpret the nature of bonding and electronic structures of these complexes.

Keywords: cobaltaborane; decaborane; eleven-vertex cluster; *nido* cluster; metallaborane; mixed-metal cluster; ten-vertex cluster

1. Introduction

Polyhedral cage expansion for the synthesis of large clusters has been the objective of boron-rich metallaborane and metallacarborane chemistry over the last six decades [1–6]. Molecular boron-rich clusters have found their place in many fields ranging from ceramics and polymers to boron neutron capture therapy and nanomaterials [7–10]. Those applications along with more fundamental studies of their specific and somewhat unique bonding and electronic structures have been the driving force towards the development of this chemistry [7,11,12]. In particular, following the pioneering work of Hawthorne et al. [13], several groups such as those of Evans [14], Welch [15], Xie [16,17], and ours [18–20] have contributed in enriching the library of the large 12–16 vertex single cage polymetalla(hetero)borane clusters over the years. The already extensive array of metallaborane clusters continues to grow in direct proportion with the advent of novel synthetic methods [9,11,17,21–33]. However, it is difficult to come up with an integrated scheme aimed at the synthesis of polyhedra bearing definite geometry and composition. This is largely due to the undefined and uncontrolled nature of cluster growth from metal synthons or small preformed clusters. Even the most sought-after strategies like condensation involving

monoborane reagents, insertion or fragmentation involving borane or metal carbonyl fragments and cluster fusion [34] rarely exhibit metallaboranes with a high metal–to–boron ratio [35–39].

Among the several strategies aimed towards cluster expansion that have been conceived over the years, the reaction of cyclopentadienyl halides or hydrides with monoborane reagents such as $\text{BH}_3 \cdot \text{THF}$ (THF = tetrahydrofuran), $[\text{BHCl}_2 \cdot \text{SMe}_2]$, or $[\text{LiBH}_4 \cdot \text{THF}]$, is a strategy that has been thoroughly optimized [40,41] and has proven to be very useful for yielding a variety of higher vertex metallaborane clusters adopting unique polyhedral cage geometries and structural features [41–45]. Although, in most cases, the metallaboranes are generated in small yields with a low metal–to–boron ratio, it was the strategy that involved pyrolyzing $[\text{Cp}^*\text{RhCl}_2]_2$ in large excess of $[\text{BH}_3 \cdot \text{THF}]$, that allowed us to isolate 15- and 16-vertex rhodaborane clusters [18]. Although fused clusters [46] or single cage clusters bearing 5–11 vertices are reported with the cobalt system [20,46–52], isolation of analogous single cage supracosahedral cobaltaboranes has not been successful up until now despite the fact that both rhodium and cobalt are group-9 metals. Indeed, our recent reports include the formation of a range of high-nuclearity cobaltaborane clusters, such as the hypoelectronic 9-vertex *closo*- $[(\text{Cp}^*\text{Co})_2\text{B}_7\text{H}_6\text{OMe}]$, hypoelectronic octadecahedral 11-vertex *closo*- $[(\text{Cp}^*\text{Co})_3\text{B}_8\text{H}_7\text{R}]$ (R = H or Me), and icosahedral 12-vertex *closo*- $[(\text{Cp}^*\text{Co})_3\text{B}_8\text{H}_8\text{S}]$ species obtained from the reaction of $[\text{Cp}^*\text{CoCl}]_2$ with $[\text{LiBH}_4 \cdot \text{THF}]$ and subsequent thermolysis with 2-mercaptobenzothiazole in toluene [50]. Our renewed quest for higher nuclearity cobaltaboranes made us look for modified synthetic strategies and although the objective of isolating a single cage supracosahedral cobaltaborane was not achieved, the treatment of $[\text{Cp}^*\text{CoCl}]_2$ with $[\text{LiBH}_4 \cdot \text{THF}]$ followed by photolysis with excess $\text{BH}_3 \cdot \text{THF}$ afforded the 11-vertex-(hyper)*nido*- $[(\text{Cp}^*\text{Co})_3\text{B}_8\text{H}_{10}]$ cluster (**1**). Group-9 metallaboranes have continually monopolized the field not only for novelty in geometries but also for the possibility to draw on the open cage molecules like $[(\text{Cp}^*\text{M})_2\text{B}_6\text{H}_{10}]$ [M = Co and Rh] and $[(\text{Cp}^*\text{Rh})_2\text{B}_8\text{H}_{12}]$ for further reactivities [53]. We have ourselves contributed significantly to this area by enriching the library of mono- and dicobaltadecaborane(14) analogues in the past [50–52]. Most recently, we have explored and reported the chemistry of dicobaltaoctaborane(12) with chalcogenated borohydride, $\text{Li}[\text{BH}_2\text{E}_3]$ [E = S, Se, or Te] which resulted in the characterization of novel chalcogenated analogues of dicobaltadecaborane(14) [54]. Careful analysis of the reaction between $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{H}_{10}]$ and $\text{Li}[\text{BH}_2\text{S}_3]$ led to the isolation of 2,4- $[(\text{Cp}^*\text{Co})_2\text{B}_8\text{H}_{12}]$ (**2**), a new dicobaltadecaborane(14) analogue. The main results are presented in this article.

2. Results and Discussion

2.1. Reaction of $(\text{Cp}^*\text{CoCl})_2$ with $[\text{LiBH}_4 \cdot \text{THF}]$ and $[\text{BH}_3 \cdot \text{THF}]$

The reaction of $[\text{Cp}^*\text{CoCl}]_2$ with an eight-fold excess of $[\text{LiBH}_4 \cdot \text{THF}]$ followed by photolysis with excess of $\text{BH}_3 \cdot \text{THF}$ at room temperature for 16 h led to the formation of a green crystalline solid in 10% yield which was characterized as a novel open-faced 11-vertex cobaltaborane, (hyper)*nido*- $[(\text{Cp}^*\text{Co})_3\text{B}_8\text{H}_{10}]$ (**1**). The reaction also yielded cobaltaboranes reported in the recent past like $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{H}_{10}]$ and $[(\text{Cp}^*\text{Co})\text{B}_9\text{H}_{14}]$ [52] (Scheme 1) and a few other compounds which could not be isolated due to lesser yields and transient natures. Preparative thin-layer chromatography (TLC) allowed separation of **1** from the reaction mixture and hence enabled the characterisation of the pure compound. Multinuclear NMR (see Supplementary Materials Figures S1–S4 for spectra) and IR spectroscopies and solid-state structure determination by X-ray diffraction analysis helped establish the composition and structure of **1**. A detailed account of the spectroscopic and structural characterizations of **1** follows.

$[(\text{Cp}^*\text{Co})_3\text{B}_8\text{H}_{10}]$, **1**. The room temperature $^{11}\text{B}\{^1\text{H}\}$ NMR of **1** shows the presence of four resonances between 71.4 and 19.7 ppm. The $^1\text{H}\{^{11}\text{B}\}$ NMR spectrum of **1** suggests the existence of two different Cp^* environments appearing at 1.9 and 1.7 ppm with a relative ratio of 1:2. This is also corroborated by the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum. In addition to the chemical shifts corresponding to B-H_i protons, the $^1\text{H}\{^{11}\text{B}\}$ NMR spectrum also

shows a sharp upfield resonance in the hydride region at $\delta = -20.43$ ppm which may typically be arising due to two equivalent Co-H-B protons. The infrared (IR) spectrum shows broad bands around 2438 cm^{-1} owing to stretching frequencies of the terminal B-H_t bonds. Although the spectroscopic data indicated the formation of a large cluster, they were not sufficient to help conceptualize the actual identity of **1**. A clear identification was obtained only after the crystal structure determination of **1** which was carried out with crystals obtained by slow evaporation of a concentrated hexane/CH₂Cl₂ (90:10) solution of **1** kept at $-10\text{ }^{\circ}\text{C}$.

Scheme 1. Synthesis of the open-faced tricobaltaborane cluster **1**.

The molecular structure of **1** (Figure 1) adopts a classical 11-vertex *nido* core that can be formally generated by the removal of an apical vertex of the ubiquitous 12-vertex icosahedron (Figure 2). The molecule has two minor disordered components with atoms B8 and B8', each with 50% occupancy. Despite the lack of precision in some of the bond distances and angles of the cluster owing to the restraints set to resolve this disorder, the crystallographic data reasonably allow a clear determination of the structure. Only one of the residues (with B8') is discussed and shown in Figure 1. The five atoms of the open face (Co1, B4, B5, B7, and B8') of the cluster are four-connected vertices while the remaining six ones are all five-connected vertices (Figure 1). This is in agreement with the NMR results discussed above which indicate that the higher chemical shifts in the ¹¹B NMR spectrum corresponds to the high connected B atoms with the chemical shifts for B1 and B2 accidentally eclipsing at 71.4 ppm thus displaying four resonances in the ratio 2:2:2:2. A crystallographic mirror plane passing through the atoms Co1, B1, and B2 bisects the molecule into two symmetrical entities, thereby rendering the chemical environments of Cp* ligands attached to Co2 and Co3 as equivalent.

The polyhedral cage geometry of cluster **1** looks reminiscent of that of classical 11-vertex *nido* geometry of related clusters such as [C₂B₉H₁₁]²⁻, [(Cp*Rh)₃B₈H₉(OH)₃] [55], [*nido*-7,8,9-PC₂B₈H₁₁] [56], [8,8-η²-{η²-(BH₃)·dppm}-*nido*-8,7-RhSB₉H₁₀] [57], [9,9-η²-{η²-(BH₃)·dppm}-*nido*-9,7,8-RhC₂B₈H₁₁] [57], and [(μ-PPh₂)(PPh₃)₂Pt₂B₉H₆(OⁱPr)₃] [58] for instance which all possess 13 skeletal electron pairs (SEP), i.e., (n + 2) SEPs if n is the number of occupied vertices according to the Polyhedral Skeletal Electron Pair Theory (PSEPT) [59]. Interestingly, however, with only 12 skeletal electron pairs (SEPs), cluster **1** is two electrons short of the formal (n + 2) SEP count expected for *nido* clusters as required by the PSEPT [59]. As stated earlier, in addition to the BH_t and Cp* protons, the ¹H(¹¹B) NMR spectrum shows the presence of only a single resonance for two bridging Co-H-B protons. The presence of two B-H-B protons which would have afforded a *nido* species with the “expected” electron count could not be traced from ¹H NMR.

To the best of our knowledge cluster **1** is the first example of electron-poor 11-vertex–12-SEP (hyper)*nido* species of this kind in the metallaborane cluster domain. Nevertheless, isoelectronic and isostructural examples are known in metallocarborane chemistry. Indeed, cluster **1** can be compared both electronically and structurally to some 11-vertex–12-SEP *nido* clusters such as [9,9-L₂-*nido*-9,7,8-MC₂B₈H₁₁] (**I**: L = PPh₃, M = Ir; **II**: L = PEt₃, M = Rh) [60] and [8,8-(PPh₃)₂-*nido*-8,7-RhSB₉H₁₀] (**III**) [61,62] (Chart 1). 11-vertex–12-SEP metalla(hetero)borane compounds exist such as [1-PPh₃-{1,3-(μ-dppm)}-*isonido*-1,2-RhSB₉H₈] (**IV**; dppm = CH₂(PPh₂)₂) [63,64], or [1,1,1-(H)(PMe₃)₂-*isonido*-1,2-IrSB₉H₉] (**V**) [65] (Figure 3), but they are not isostructural with **1**. While the latter is

generated from the icosahedron by removing one vertex (Figure 2), the geometry reported for the 11-vertex *isonido* clusters [63–65] is derived from an 11-vertex octadecahedron by the removal of one connectivity of the apical vertex thereby generating a distorted quadrilateral open face (D; top of Figure 3).

Figure 1. Molecular structure and atom labels of one of the residues of **1**. Selected bond lengths (Å) and bond angles (°) of **1**: B1–B2 1.82(2), B1–Co3 2.051(14), B1–Co2 2.063(16), B2–Co3 2.084(13), B6–B7 1.78(2), B4–Co1 2.067(14), B7–Co1 2.030(14), B7–B8'–B5 113.0(17), and B7–Co1–B4 87.4(6). Co–H–B bridging hydrogens could not be located.

Figure 2. Schematic representation of stepwise generation of the cluster framework of **1** (B) from an icosahedron (A).

Density functional theory (DFT) calculations were carried out at the B3LYP/LANL2DZ level of theory (see computational details in Section 3) on model compound **1'** (Cp analogue of **1**) to analyse the electronic structure and nature of bonding in the electron deficient molecule **1**. Optimized bond distances in **1'** are in accordance with those experimentally measured for the solid-state structure of **1** (Table S1). The molecular orbital (MO) analysis of **1'** (Table S2) shows a large energy gap of 2.79 eV between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) in agreement with the electron count of 12 SEPs and the fact that only two bridging hydrogen atoms are present in the structure. The HOMO of **1'** is mainly localized on the metal centres and the five-connected inner-core boron atoms, whereas the LUMO is predominantly localized on the metal centres with considerable participation of the boron atoms of the open face of the cluster (Figure 4). We may wonder if cluster **1** could be reduced and reach the expected

count of 13 SEPs to obey the PSEPT. It turns out that the LUMO + 1 is energetically close to the LUMO, separated only by 0.4 eV. This indicates that reduction of **1** is unlikely.

2.2. Reactivity of $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{H}_{12}]$ with $\text{Li}[\text{BH}_2\text{S}_3]$

Reactions of the open-cage dicobaltoctaborane(12) analogue $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{H}_{12}]$ with chalcogenated borohydride $\text{Li}[\text{BH}_2\text{E}_3]$ ($\text{E} = \text{S}, \text{Se}, \text{or Te}$) which were recently carried out in our group, resulted in the formation of novel chalcogenated analogues of dicobaltadecaborane(14), namely $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{E}_2\text{H}_6]$ ($\text{E} = \text{S}, \text{Se}, \text{or Te}$) [54]. The room temperature reaction between $[(\text{Cp}^*\text{Co})_2\text{B}_6\text{H}_{12}]$ and $\text{Li}[\text{BH}_2\text{S}_3]$ yielded another compound which could not be isolated earlier due to less yield. Performing the reaction at a larger scale followed by careful analysis of the reaction mixture led to the isolation of $2,4-[(\text{Cp}^*\text{Co})_2\text{B}_8\text{H}_{12}]$ (**2**), i.e., a novel dicobaltadecaborane(14) analogue (Scheme 2). This compound was characterized by ^1H , $^{11}\text{B}\{^1\text{H}\}$ and $^{13}\text{C}\{^1\text{H}\}$ NMR (Figures S5–S8) and IR spectroscopies, mass spectrometry (Figure S9), and single-crystal X-ray diffraction analysis.

Scheme 2. Synthesis of a symmetric dicobaltaborane analogue of decaborane(14).

Dicobaltadecaborane(14) analogue, **2**. Cluster **2** was isolated as a yellow solid in 15% yield. The mass spectrometric data for **2** showed molecular ion peaks at m/z 487.2692 which corresponds to the molecular formula $[\text{C}_{20}\text{H}_{42}\text{B}_8\text{Co}_2]^+$. The $^{11}\text{B}\{^1\text{H}\}$ NMR showed chemical shifts at $\delta = 26.6, 11.4,$ and 5.6 ppm, whereas ^1H NMR showed a single chemical shift for 30 Cp^* protons at $\delta = 1.69$ ppm, and additionally, chemical shifts at $\delta = 4.38, 2.94,$ and 2.31 ppm which correspond to $\text{B}-\text{H}_t$ protons. A distinct up-field resonance was observed at $\delta = -4.25$ ppm which may be assigned to four equivalent $\text{B}-\text{H}-\text{B}$ bridging protons. The chemical shifts displayed in the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum also corroborated with a single Cp^* environment in the molecule. The infrared (IR) spectrum showed broad bands centered around 2493 cm^{-1} owing to stretching frequencies of the terminal $\text{B}-\text{H}$ bonds.

Slow evaporation of a concentrated hexane/ CH_2Cl_2 (80:20) solution of **2** kept at -10°C yielded crystals suitable for X-ray diffraction analysis. The solid-state X-ray structure of **2** (Figure 5), determined by single-crystal X-ray diffraction measurements clearly shows that it is a 10-vertex open *nido*-dicobaltaborane which is in absolute agreement with the spectroscopic as well as mass spectrometric data. It is apparent from its solid state X-ray structure that compound **2** adopts the same structural arrangement as the symmetric dimetalla *nido*-2,4- $[(\text{Cp}^*\text{M})_2\text{B}_8\text{H}_{12}]$ ($\text{M} = \text{Rh}$ and Ir) [27,55] previously reported, analogues of decaborane(14). In the structure, a crystallographic mirror plane including the B_6-B_8 vector bisects the molecule into two equivalent $\{\text{CoB}_3\}$ units. As a result, the two Co atoms that reside on either side of the crystallographic mirror plane are chemically equivalent and hence correspond to the presence of single Cp^* environment in the ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra. The bridging hydrogen atoms lie on the open face of the six-membered ring and their presence is confirmed both by ^1H NMR and X-ray diffraction studies. We noted that the average $\text{B}-\text{B}$ bond length in **2** is somewhat shorter as compared to the Rh and Ir analogues [27,55] and follows the trend ($\text{Co} < \text{Rh} < \text{Ir}$) down the triad. A $\{\text{Cp}^*\text{Co}\}$ unit being isolobal with a BH unit, the cluster is isostructural and isoelectronic with *nido*-decaborane(14) which can be generated from the removal of the six-connected apical vertex of an octadecahedron (see bottom of Figure 3). Indeed, **2** can be regarded as a 10-vertex *nido* metallaborane cluster with 12 SEPs, as expected according to the PSEPT. **2** is then a new member of the series of ten-vertex–12-SEP polyhedral borane, carborane, or metallaborane clusters having the same SEP count and geometry. We have tried to compare its structural data and chemical shift values with a set of comparable cobaltaboranes with

the formal electron count of 12 SEPs (Table 1). The unique feature of this reaction here (Scheme 2) is the insertion of two BH units in octaborane(12) that leads to cluster growth from 8 to 10 vertices.

Figure 5. Molecular structure and atom labels for **2**: frontal view (left) and bottom angular view (right, Cp* ligands attached to Co are omitted for clarity). Selected bond lengths (Å) and bond angles (°): B1–Co1 1.972(5), B2–B3 1.971(7), B2–Co1 2.043(5), B3–B4 1.807(8), B3–Co2 2.043(4), B5–Co2 2.041(5), B7–Co1 2.046(4), B3–B2–Co1 115.5(2), B4–B3–B2 116.3(4), B3–B4–B5 103.9(3), and B2–Co1–B7 89.1(2).

In order to acquire an insight into the structure and bonding of **2**, we further did DFT calculations at the B3LYP/LANL2DZ level of theory (see computational details in Section 3 on model **2'** (Cp analogue of **2**) as well as on its group-9 metallaborane model analogues

3' (Cp analogue of 2,4-[(Cp**Rh*)₂B₈H₁₂]) and **4'** (Cp analogue of 2,4-[(Cp**Ir*)₂B₈H₁₂]) for comparison. The optimized geometrical parameters obtained for **2'** compare fairly well with the corresponding crystallographically characterized data of **2** (Table S1). Additionally, the gauge-including atomic orbitals-density functional theory (GIAO-DFT calculated ¹¹B chemical shift values agree well with those observed experimentally (Table 2) and are of sufficient accuracy to confirm assignments that are consistent with the empirical ones based simply on boron connectivity and environment (see above).

Table 2. Experimentally observed and calculated ¹H and ¹¹B chemical shifts for **2–4** species and **2'–4'** models, respectively.

| Cluster | ¹ H NMR δ (ppm) | | ¹¹ B NMR δ (ppm) | | Ref. |
|---------|----------------------------|-------|-----------------------------|------------------|------------|
| | Expt. | Calc. | Expt. | Calc. | |
| 2/2' | −4.25 | −6.22 | 26.6, 11.4, 5.6 | 20.0, 11.0, 3.0 | This work |
| 3/3' | −3.52 | −5.43 | 21.1, 9.4, 1.9 | 16.2, 6.5, 0.8 | 56 (expt.) |
| 4/4'' | −3.73 | −5.45 | 1.8, −0.2, −12.9 | 7.3, −1.7, −11.0 | 27 (expt.) |

A molecular orbital analysis suggests a significant HOMO-LUMO energy gap (>4 eV) for the three compounds in the order **2' < 3' < 4'** (Figure 6). Inspection of the nodal properties of the frontier MOs reveals that HOMOs weigh heavily on the respective metal centres, while the LUMOs are delocalized both on the metal centres and the five-connected inner-core boron atoms. Metal–metal Wiberg bond indices computed for **2'**, **3'**, and **4'** are very weak and close to each other (ca. 0.06), reflecting the nonappearance of bonding interaction between the metal centres in such species.

Figure 6. Frontier molecular orbital diagram of **2'**, **3'**, and **4'** (see text). Contour value: $\pm 0.05 [e/\text{bohr}^3]^{1/2}$.

3. Materials and Methods

3.1. General Methods and Instrumentation

All of the experiments were conducted under an argon atmosphere using standard Schlenk and glove-box techniques. Solvents were distilled prior to use under argon. Cp*H, CoCl₂, *n*-BuLi in hexane, LiBH₄ (2.0 M in THF), BH₃·THF, and S powder were used as received (Sigma Aldrich, Bangalore, India). (Cp*CoCl)₂ [67,68], [(Cp*Co)₂B₆H₁₀] [52], and Li[BH₂S₃] [69,70] were synthesized as per literature. Thin-layer chromatography, using silica gel TLC plates by Merck supported with 250-μm diameter aluminum, was done to separate the reaction mixtures. A 500 MHz Bruker FT-NMR spectrometer (Bruker, Billerica, MA, USA), JASCO FT/IR-4100 (JASCO, India) and Agilent Technologies: 6545-Q-TOF LC/MS (Agilent, Santa Clara, CA, USA) spectrometer were used respectively to record NMR, Infrared (IR) spectra, and ESI (Electrospray Ionization) mass. In ¹H NMR spectra, the chemical shifts for residual protons in the deuterated solvents were used as reference

(CDCl₃, δ = 7.26 ppm, C₆D₆, δ = 7.16) while a sealed tube containing [Bu₄N(B₃H₈)] [71] in benzene-*d*₆ (δ_B , ppm, −30.07) was used as an external reference for ¹¹B{¹H} NMR spectra. The light source for the photoreaction described in this report was Oriel Instrument with a 500 W Hg/Xe arc lamp equipped with liquid and colored glass filters, irradiating at 280–780 nm.

Synthesis of **1**: [Cp*CoCl]₂ (0.1 g, 0.22 mmol) was suspended in toluene (15 mL) in a flame-dried Schlenk tube and was cooled to −78 °C, [LiBH₄·THF] (0.6 mL, 1.20 mmol) was added to it and the reaction mixture was allowed to warm slowly to room temperature and was left to stir for another hour. [BH₃·THF] (3 mL) was added to the reaction mixture and the resultant mixture was slowly warmed to room temperature was allowed to stir for 30 min, and finally kept for photolysis at room temperature for 12 h. After completion of the reaction (monitored by TLC), the solvent was removed under vacuum and the residue was dissolved in hexane and passed through Celite. The solvent was evaporated under vacuum and the residue was purified using preparative silica-gel TLC plates by eluting with hexane/CH₂Cl₂ (80:20) mixture that yielded green solid **1** (0.010 g, 10%) and known red solids [(Cp*Co)₂B₆H₁₀] (0.025 g, 24%), [(Cp*Co)₃B₄H₄] (0.018 g, 19%), and a few compounds which could not be isolated. The known cobaltaboranes were characterized with reference to their spectroscopic data reported earlier.

1: ¹¹B NMR (160 MHz, C₆D₆, 22 °C): δ = 71.5, 31.4, 24.5, 19.7 ppm; ¹H{¹¹B} NMR (500 MHz, C₆D₆, 22 °C): δ = 8.08 (br, 4H, BH_t), 5.16 (s, 2H, BH_t), 4.08 (s, 2H, BH_t), 1.94 (s, 15H, Cp*), 1.70 (s, 30H, Cp*) −20.43 (br, 2H, Co-*H*-B) ppm; ¹³C NMR (100 MHz, C₆D₆, 22 °C) = 96.0, 93.4 (C₅Me₅), 10.4, 9.6 ppm (C₅Me₅); IR (dichloromethane): $\bar{\nu}$ = 2438 (BH_t) cm^{−1}.

Synthesis of **2**: In a flame-dried Schlenk tube, [(Cp*Co)₂B₆H₁₀] (0.05 g, 0.107 mmol) was suspended in 5 mL of dry THF at room temperature. A freshly prepared solution of Li[BH₂S₃] in THF (10 mL, 0.428 mmol) was added dropwise to the red solution of [(Cp*Co)₂B₆H₁₀]. The reaction mixture was allowed to stir at room temperature for 24 h. The solvent was dried under vacuum and the residue was extracted into *n*-hexane/CH₂Cl₂ (85:15 *v/v*) mixture and passed through Celite. After removal of the solvent, the residue was subjected to chromatographic work-up by using TLC plates. Elution with an *n*-hexane/CH₂Cl₂ (85:15 *v/v*) mixture yielded the air-stable yellow solid (Compound **2**) (0.020 g, 38%) and the known compound [(Cp*Co)₂B₆H₆S₂] (0.016 g, 28 %) [57].

2: MS (ESI+): *m/z* calculated for C₂₀H₄₂B₈Co₂⁺ 487.2747, found 487.2692; ¹¹B NMR (160 MHz, CDCl₃, 22 °C): δ = 26.6, 11.4, 5.6 ppm; ¹H NMR (500 MHz, CDCl₃, 22 °C): δ = 4.38 (s, 2H, BH_t), 2.94 (s, 2H, BH_t), 2.31 (s, 4H, BH_t), 1.69 (s, 30H, Cp*), −4.25 (br, 4H, B-*H*-B) ppm; ¹³C NMR (100 MHz, CDCl₃, 22 °C) = 97.0 (C₅Me₅), 9.8 ppm (C₅Me₅); IR (dichloromethane): $\bar{\nu}$ = 2493 (BH_t) cm^{−1}.

3.2. Single Crystal X-ray Diffraction Analysis

Crystallographic and structural refinement data for **1** and **2** are given in Table 3. Bruker AXS Kappa APEXII CCD diffractometer, (Bruker, Billerica, MA, USA) with graphite monochromatic Mo K α (λ = 0.71073 Å) radiation at 296 K was used to collect and integrate crystal diffraction data. Heavy atom methods like SHELXT-2014 and SHELXS-97 [72–74] were used to solve the structures while SHELXL-2018 and SHELXL-2014 [73] were used for structure-refinements, respectively. Olex2 [75] was used for drawing molecular structures.

3.3. Computational Details

Gaussian 09 program package [76] was used for geometry optimizations of all model clusters. Computations were done with the Cp ligands in place of Cp* to reduce the computational effort (for optimized model clusters see Figures S10–S13). Gas-phase optimizations without any solvent effect or symmetry constraints, were done with the hybrid Becke–Lee–Yang–Parr (B3LYP) functional [77] in combination with the LANL2DZ (Los Alamos National Laboratory 2 Double-Zeta) basis set [78] for all the atoms from the EMSL (Environmental Molecular Sciences Laboratory) Basis Set Exchange Library [79]. Frequency calculations were carried out for all structures to check the nature of the stationary states

and the absence of any imaginary frequency to confirm that the optimized geometries were genuine minima on the potential energy hypersurface. NMR chemical shifts were computed by employing the gauge-including atomic orbitals (GIAOs) method [80–82] using the optimized geometries at the B3LYP/LANL2DZ level. Chemical shifts corresponding to ^{11}B NMR were computed in relation to B_2H_6 (B3LYP shielding constant for ^{11}B NMR: 83.6 ppm) and were then converted to the standard $[\text{BF}_3 \cdot \text{OEt}_2]$ scale by adding 16.6 ppm (the experimental δ (^{11}B) value of B_2H_6) to the computed values. ^1H NMR chemical shift calculations were done with TMS (SiMe_4) as the internal standard. Chemcraft [83] was used for generating orbital graphics and optimized structure plots. Natural Bond Orbital (NBO) analyses [84] allowed for arrival of the Wiberg Bond Indices (WBI) [85].

Table 3. Crystallographic and structural refinement data for **1** and **2**.

| Compound | 1 | 2 |
|--|---|---|
| CCDC No. | 2043679 | 2060786 |
| Empirical formula | $\text{C}_{30}\text{H}_{53}\text{B}_8\text{Co}_3$ | $\text{C}_{20}\text{H}_{42}\text{B}_8\text{Co}_2$ |

| Parameters | 452 | 329 |

4. Conclusions

Results described in this article have demonstrated the scope of new methodologies for the synthesis of high-nuclearity cobaltaborane clusters. Firstly, one of the new routes described here has led to the isolation of a novel and unprecedented 11-vertex–12-SEP disobedient cobaltaborane cluster with a (*hyper*)*nido* M_3B_8 core. The second route has allowed for synthesis and characterization of a classic example of sequentially generated higher nuclearity cluster with a 10-vertex–12-SEP *nido* core via cluster growth on a pre-formed template. Indeed, cobaltaboranes and cobaltaheteroboranes constitute a showcase for dynamic and unique structural features and as a result, we are always on the lookout for possibilities of generating novel sophisticated cobaltaborane frameworks. Amongst the several synthetic strategies that are recognized in this domain, the applicability of the ones reported here may be vital and might lead to the generation of sophisticated high-nuclearity metallaborane frameworks of other group-9 metals. The unusual formation of **1** and the open-faced geometries of both **1** and **2** should imply enhanced reactivity to such species. Further efforts are currently devoted to that purpose.

Supplementary Materials: Some supplementary information is available online at <https://www.mdpi.com/article/10.3390/inorganics9040028/s1>. It contains ^1H , $^{11}\text{B}\{^1\text{H}\}$, $^{13}\text{C}\{^1\text{H}\}$ NMR and mass spectra (Figures S1–S9); CIF and checkCIF files as well as the xyz coordinates of the DFT optimized model clusters (Figures S10–S13), selected bond parameters for clusters **1'** and **2'** and their Wiberg bond indices (WBI) (Table S1) as well as calculated HOMO and LUMO energy levels and HOMO–LUMO gaps of **1'–4'** (Table S2).

Author Contributions: K.P. and C.N. formulated and planned the experiments; K.P. and C.N. carried out the synthesis and spectroscopic analyses and discussed the results with S.G. and J.-F.H.; K.P. and C.N. organized the manuscript with guidance from S.G. and J.-F.H.; S.G. supervision, S.G. project administration. All authors have read and agreed to the published version of the manuscript.

Funding: This work was supported by CSIR (Scheme No. 01 (2939)/18/EMR-II), New Delhi, India.
